# Thinking in Parallel

**Ivan Girotto – [igirotto@ictp.it](mailto:igirotto@ictp.it)**

International Centre for Theoretical Physics (ICTP)

# Serial Programming

A problem is broken into a discrete series of instructions.  
Instructions are executed one after another.  
Only one instruction may execute at any moment in time.

# Parallel Programming

# Concurrency

The first step in developing a parallel algorithm is to decompose the problem into tasks that can be executed concurrently

- A problem is broken into discrete parts that can be solved concurrently
- Each part is further broken down to a series of instructions
- Instructions from each part execute simultaneously on different processors
- An overall control / coordination mechanism is employed

# What is a Parallel Program

# Fundamental Steps of Parallel Design

- Identify portions of the work that can be performed concurrently
- Mapping the concurrent pieces of work onto multiple processes running in parallel
- Distributing the input, output and intermediate data associated within the program
- Managing accesses to data shared by multiple processors
- Synchronizing the processors at various stages of the parallel program execution

# Type of Parallelism

- **Functional (or task) parallelism**:  
different people are performing  
different task at the same time
- **Data Parallelism**:  
different  
people are performing the same  
task, but on different equivalent and  
independent objects

# Process Interactions

- The effective speed-up obtained by the parallelization depend by the amount of overhead we introduce making the algorithm parallel
- There are mainly two key sources of overhead:
  1. Time spent in inter-process interactions (communication)
  2. Time some process may spent being idle (synchronization)

# Load Balancing

- Equally divide the work among the available resource: processors, memory, network bandwidth, I/O, ...
- This is usually a simple task for the problem decomposition model
- It is a difficult task for the functional decomposition model

# Effect of Load Unbalancing

# Minimizing Communication

- When possible reduce the communication events:
  - group lots of small communications into large one
  - eliminate synchronizations as much as possible.  
Each synchronization level off the performance to that of the slowest process

# Overlap Communication and Computation

- When possible code your program in such a way that processes continue to do useful work while communicating
- This is usually a non trivial task and is afforded in the very last phase of parallelization
- If you succeed, you have done. Benefits are enormous

# Granularity

- Granularity is determined by the decomposition level (number of task) on which we want divide the problem
- The degree to which task/data can be subdivided is limit to concurrency and parallel execution
- Parallelization has to become “topology aware”
  - coarse grain and fine grained parallelization has to be mapped to the topology to reduce memory and I/O contention
  - make your code modularized to enhance different levels of granularity and consequently to become more “platform adaptable”

# Limitations of Parallel Computing

- Fraction of serial code limits parallel speedup
- Degree to which tasks/data can be subdivided is limit to concurrency and parallel execution
- Load imbalance:
  - parallel tasks have a different amount of work
  - CPUs are partially idle
  - redistributing work helps but has limitations
  - communication and synchronization overhead

# Shared Resources

- In parallel programming, developers must manage exclusive access to shared resources
- Resources are in different forms:
  - concurrent read/write (including parallel write) to shared memory locations
  - concurrent read/write (including parallel write) to shared devices
  - a message that must be send and received

The Abdus Salam  
International Centre  
for Theoretical Physics

# Fundamental Tools of Parallel Programming

# MPI Program Design

- Multiple and separate processes (can be local and remote) concurrently that are coordinated and exchange data through “messages”
  - => a “share nothing” parallelization
- Best for coarse grained parallelization
- Distribute large data sets; replicate small data
- Minimize communication or overlap communication and computing for efficiency
  - => Amdahl's law: speedup is limited by the fraction of serial code plus communication

# Phases of an MPI Program

1. Startup
  - Parse arguments (mpirun may add some!)
  - Identify parallel environment and rank of process
  - Read and distribute all data
2. Execution
  - Proceed to subroutine with parallel work (can be same of different for all parallel tasks)
3. Cleanup

CAUTION: this sequence may be run only once

# Programming Parallel Paradigms

- Are the tools we use to express the parallelism for on a given architecture (see also SPMD, SIMD, etc... )
- They differ in how programmers can manage and define key features like:
  - parallel regions
  - concurrency
  - process communication
  - synchronism

# Parallelism - 101

- there are two main reasons to write a parallel program:
  - access to larger amount of memory (aggregated, going bigger)
  - reduce time to solution (going faster)

# Static Data Partitioning

**The simplest data decomposition schemes for dense matrices are 1-D block distribution schemes.**

row-wise distribution

|       |
|-------|
| $P_0$ |
| $P_1$ |
| $P_2$ |
| $P_3$ |
| $P_4$ |
| $P_5$ |
| $P_6$ |
| $P_7$ |

column-wise distribution

|       |       |       |       |       |       |       |       |

| $P_0$ | $P_1$ | $P_2$ | $P_3$ | $P_4$ | $P_5$ | $P_6$ | $P_7$ |
|-------|-------|-------|-------|-------|-------|-------|-------|

# Distributed Data Vs Replicated Data

- Replicated data distribution is useful if it helps to reduce the communication among process at the cost of bounding scalability
- Distributed data is the ideal data distribution but not always applicable for all data-sets
- Usually complex application are a mix of those techniques => distribute large data sets; replicate small data

# Global Vs Local Indexes

- In sequential code you always refer to global indexes
- With distributed data you must handle the distinction between global and local indexes (and possibly implementing utilities for transparent conversion)

|            |                                                        |   |   |   |                                                        |   |   |   |                                                        |   |   |   |
|------------|--------------------------------------------------------|---|---|---|--------------------------------------------------------|---|---|---|--------------------------------------------------------|---|---|---|

#example for the OpenMPI implementation
./prog.x --input input_${OMPI_COMM_WORLD_RANK}.dat

[igirotto@localhost]$ mpirun -np 400 ./my_shell_wrapper.sh
```

# Easy Parallel Computing

- Farming, embarrassingly parallel
  - Executing multiple instances on the same program with different inputs/initial cond.
  - Reading large binary files by splitting the workload among processes
  - Searching elements on large data-sets
  - Other parallel execution of embarrassingly parallel problem (no communication among tasks)
- Ensemble simulations (weather forecast)
- Parameter space (find the best wing shape)

# Parallel I/O

# Parallel I/O

# Parallel I/O

**MPI I/O & Parallel I/O Libraries (Hdf5, Netcdf, etc...)**

## Parallel File System

# Make Use Freely Available Parallel Libraries

- Scalable Parallel Random Number Generators Library (SPRNG)
- Parallel Linear Algebra (ScaLAPACK)
- Parallel Library for Solution of Finite Elements (dealii)
- Parallel Library for FFT (FFTW)
- Parallel Linear Solver for Sparse Matrices (PETSc)

# Measure of Parallelism

- evaluation of the performance improvement is not always straightforward, specially considering at the increasing the problem complexity

# Scaling

- *Scaling* is how the performance of a parallel application changes as the number of processors is increased
- There are two different types of scaling:
  - *Strong Scaling* – total problem size stays the same as the number of processors increases
  - *Weak Scaling* – the problem size increases at the same rate as the number of processors, keeping the amount of work per processor the same
- Strong scaling is generally more useful and more difficult to achieve than weak scaling

# Strong scaling

Example runtime vs No. of processors

# How do we evaluate the improvement?

- We want estimate the amount of the introduced overhead  $\Rightarrow T_o = n_{pes} T_P - T_S$
- But to quantify the improvement we use the term **Speedup**:

$$S_p = \frac{T_S}{T_P}$$

# Speedup

Caspian Test Case 210 x 192 x 18 - 1 Month Simulation

Caspian Test Case 210 x 192 x 18 - 1 Month Simulation

# Efficiency

- Only embarrassing parallel algorithm can obtain an ideal Speedup
- The **Efficiency** is a measure of the fraction of time for which a processing element is usefully employed:

$$E_p = \frac{S_p}{p}$$

# Efficiency

Caspian Test Case 210 x 192 x 18 - 1 Month Simulation

Caspian Test Case 210 x 192 x 18 - 1 Month Simulation

# Scalability Limits

- Amdahl's law (there is a serial part which is not effected)
- Parallelism introduces overhead due to communication, synchronization, additional operations (I/O, memory copies, reordering, etc...)
- Sometimes the limit of scalability can be somehow predicted:
  - is there enough work for any process?
- When considering complex problem not all part of the problem scale eqaully

### Strong Scaling 30 spins

# Timing

- Time measurement becomes a relevant task:
- `MPI_WTIME()`
- `Clock`
- `Seconds()`

convergence NOT achieved after 5 iterations: stopping
